

Quorumly

AI-summarized, reputation-weighted governance voting for Solana DAOs

The Problem & Our Solution

DAOs on Solana suffer from low turnout and whale-dominated votes because proposals are long and hard to parse.

- Hundreds of active Realms DAOs face voter apathy and plutocratic capture
- Lengthy proposals discourage members from reading and participating
- Token-only voting weight lets whales dominate outcomes regardless of engagement
- Quorumly summarizes proposals with AI and blends reputation into voting weight
- Result: fairer, more informed, more engaged DAO governance

How It Works

Quorumly fetches live proposals, summarizes them, scores reputation, and lets members vote directly from one dashboard.

- User flow: connect wallet, browse AI-summarized proposals, check reputation-weighted vote, cast vote
- Fetch live proposals from Realms SDK and summarize with OpenAI API into plain-language pros/cons
- Compute reputation score from historical on-chain voting and delegation activity
- Blend token balance with reputation score to produce final voting weight
- Casting a vote submits an on-chain transaction via Realms/Anchor directly from the summary view

Built with

Solana, Realms SDK, Anchor, OpenAI API, React, TypeScript, Postgres

Why Now & What's Next

Solana governance tooling needs a fix as DAO fatigue grows; Quorumly is built to extend across the ecosystem.

Category

Infrastructure

- Realms hosts hundreds of DAOs today, but participation keeps declining
- AI summarization and reputation scoring are timely, practical fixes for governance fatigue
- Next: integrate with more governance frameworks beyond Realms
- Next: open the reputation score as a public API for other DAO tools
- Next: add delegate matching to connect passive holders with active voters
